

Business Analytics Q&A

1. Which 3 cities should the tea brand prioritize for expansion?

The brand should prioritize Bangalore (BLR), Mumbai (BOM), and Delhi (DEL).

2. Why did you choose these 3 cities?

The ranking balances customer volume, retention, average order value and purchase frequency across the core metrics.

Bangalore (BLR):

Ranks #1 on the expansion index. It has the highest retention rate at 87.40%, a strong AOV of ₹64.19, and high purchase frequency. Its strong retention makes it the strongest market to test a scalable growth playbook.

Mumbai (BOM):

Ranks #2 on the expansion index. It represents the largest proven customer base with 11,566 customers, around 79.93% retention, and consistent repeat frequency. This makes it an important high-volume market with an established customer base.

Delhi (DEL):

Ranks #3 on the expansion index. It has the highest AOV at ₹66.51 and a large customer base of 8,789 customers. Improving retention or purchase frequency here could create a significant revenue opportunity.

3. Which city has the biggest existing customer base but retention problem?

Delhi (DEL).

Delhi has 8,789 customers and the highest AOV at ₹66.51, but its retention rate is only 73.60%.

This makes Delhi an important retention opportunity because the brand already has a large customer base and relatively high order value, but a significant proportion of customers are not being retained.

4. Which city looks small but high-value?

Bangalore (BLR).

With only 1,698 customers, Bangalore has the smallest customer base among the major cities analysed. However, it has the highest retention rate at 87.40% and a strong AOV of ₹64.19.

This makes Bangalore particularly interesting as a market where strong customer behaviour could potentially be replicated at a larger scale.

5. Which city looks strong overall according to city_expansion_score?

Bangalore (BLR).

It has the highest expansion_index_score at approximately 59.5 and ranks #1.

Its strong position comes from its high retention, purchase frequency, customer value and overall performance across the expansion metrics.

6. Which city should NOT be prioritized right now, and why?

Chennai (MAA).

Chennai ranks #4 with an expansion score of approximately 39.7.

Although it has a sizable customer base of 8,748 customers and decent retention of 83.15%, it has the lowest AOV at ₹58.51 and lower order velocity.

Based on the current metrics, Bangalore, Mumbai and Delhi offer stronger expansion opportunities.

7. What customer behaviour seems associated with retention?

Several behaviours are associated with higher retention:

Paperless billing:

Adoption is approximately 68.5% among retained customers, compared with 48.7% among non-retained customers.

Refill and doorstep delivery:

Retained customers show higher adoption of both behaviours compared with non-retained customers.

Email engagement:

Retained customers have higher email open and click-through rates.

Order frequency and spend:

Retained customers show higher order frequency and more sustained order values.

These are associations in the data, not proof that any individual behaviour directly causes retention.

8. What would you recommend the founder do before entering a new city?

First, establish reliable refill and subscription logistics so that recurring orders can be supported effectively.

Second, investigate the retention gap in Delhi before putting significant acquisition money into a new market. Delhi already has a large customer base and high AOV, so

understanding the reason behind the retention gap could unlock an existing growth opportunity.

Third, use Bangalore as a customer profile to investigate further. Its strong retention and customer behaviour can provide a useful hypothesis for the type of customer and experience that may work well in other markets.

9. What important business question can this dataset NOT answer?

Profitability and unit economics:

The dataset does not contain COGS, shipping costs, packaging costs, CAC or contribution margin.

Root causes of churn:

It shows retention differences but does not explain why customers leave. We do not have complaints, delivery issues, product feedback, pricing objections or taste preferences.

Product-level performance:

The dataset does not contain SKU, flavour or product-level order data, so it cannot tell us which tea products perform best in each city.

Channel attribution:

It does not show whether customers came through paid ads, organic search, referrals, influencers, retail or other channels.

10. If you had to convince the founder in 30 seconds, what is your ONE main recommendation?

Stop aggressively acquiring customers in cities where retention is weak. Strengthen retention in existing high-potential markets first.

Bangalore stands out with 87.40% retention and strong order behaviour despite having a relatively small customer base. I would use Bangalore as the market to test a repeatable retention and growth playbook, while investigating refill and doorstep-led strategies because these behaviours are strongly associated with retained customers in the dataset.

11. Why Bangalore over Mumbai as the #1 priority?

Mumbai has much greater scale, with 11,566 customers, but Bangalore shows stronger retention and customer value.

Bangalore has 87.40% retention compared with Mumbai's 79.93%, and its AOV is ₹64.19 compared with Mumbai's ₹60.56.

Bangalore also has only 1,698 customers, leaving room to test whether its stronger retention pattern can be replicated at a larger scale.

Therefore, I would prioritize Bangalore as the market to test and refine a scalable growth playbook, while continuing to recognize Mumbai as an important high-volume market.

12. Delhi has a retention problem. What would you investigate first?

I would start by investigating the delivery and fulfillment experience.

Delhi has the highest AOV at ₹66.51 and a large customer base of 8,789 customers, but retention is only 73.60%.

However, the current dataset does not contain delivery times, RTOs, complaints or packaging information. So delivery would be my first hypothesis to investigate, not a conclusion.

I would validate:

- Delivery timelines and SLA adherence
- Packaging or damage issues
- RTO and failed-delivery rates
- Customer complaints and reviews
- Product experience
- Post-purchase engagement

13. Why should I trust this if it is not actual Dorje Teas data?

“I would not treat this as Dorje Teas' actual performance data. I would treat it as a demonstration of the analytical framework.

The public dataset allowed me to identify patterns around retention, customer behaviour and city-level opportunity. The next step would be to test whether those patterns hold in Dorje's actual customer data.

I have already built the SQL and Power BI workflow, so the same framework can be applied once the real data is available.”

The objective is not to claim conclusions about Dorje Teas without internal data, but to demonstrate how I approach a business problem and turn data into actionable questions.

14. What additional data would you request from Dorje Teas?

Product and SKU data

- SKU IDs and product variants
- Tea type or blend
- Pack sizes
- Product-level repeat purchases

Order and transaction data

- Order timestamps
- Order value
- Discounts and coupons
- Payment mode
- Shipping charges
- Order-line level data

Fulfillment and logistics

- Customer pincode or city
- Delivery timelines
- SLA adherence
- RTO rates
- Failed deliveries
- Delivery partner
- Packaging or damage information

Acquisition and customer data

- Acquisition channel
- CAC by channel
- Customer cohorts
- Reviews and feedback
- Returns and cancellations

- Churn reasons

Unit economics

- COGS
- Packaging cost
- Shipping cost
- Gross or contribution margin
- Marketing spend

This would allow the analysis to move beyond WHERE and WHO toward understanding WHAT, WHY and HOW PROFITABLY.

15. What is the #1 question you would answer on Day One with real data?

“Which acquisition-channel and product combinations generate the strongest contribution margin and fastest CAC payback?”

The public dataset provides information about customer behaviour, retention and AOV, but it does not tell us whether those sales are actually profitable.

With real data, I would connect:

Acquisition channel → Customer → Product/SKU → Order → Repeat purchase → Revenue → Costs → Contribution margin

This would help identify which combinations are genuinely worth scaling and which may be generating revenue without attractive economics.

I would then calculate LTV, CAC and payback period using Dorje Teas' actual economics rather than assuming an external benchmark.
